

Part 4 — Define the Problem

Myntra Growth Team · Wishlist-to-Purchase Conversion

Grounded in Phase 1–5 AI discovery output (17,495 relevant records) and a 36-respondent primary-research survey.

This document answers the six required questions in Part 4 of the assignment brief, then shows the evidence chain — Business Metric → Product Outcomes → AI Discovery → Primary Research → Problem Definition — that the answer was derived from, so the conclusion is traceable rather than asserted.

1. Target User Segment

Active Comparers whose comparisons go cold — users who add an item to their wishlist while actively comparing it against alternatives, but never return to close that comparison before attention decays.

Evidence for the segment:

- **segment:comparers** contributes to 9 of the top 10 AI-discovered opportunities — comparison behavior recurs across barrier types, not a one-off theme.
- “Comparing with other options” is the single most common reason for wishlisting instead of buying immediately — **61% overall, 59% among the 22 non-converters** in the survey.
- “I forgot about it” is the single most common blocker among true non-converters (**32%**, up from 19% in the full sample) — the second stage of the same failure.

2. Product Outcome We Intend to Influence

Not the final purchase-completion step. The target outcome sits upstream: the **30-day comparison-resolution rate** — the share of wishlisted items (added under an explicit comparison motive) that receive an active re-engagement and an explicit compare/decide action within roughly 14 days, before default attention-decay sets in.

This is a leading, upstream proxy for the north-star metric — it sits at **Stage A (Re-engagement) → Stage C (Comparison Resolution)** of the Part 2 funnel, not Stage E (Purchase Completion), which is where volume-based review mining pointed first.

3. Root Cause

The wishlist functions as a **passive bookmark list, not an active decision-support workspace**. When a user saves an item mid-comparison, the product:

- Captures no structured reason for the save — neither user nor product can act on the comparison later.
- Has no mechanism to pull the user back into the unresolved comparison before attention naturally decays.
- Offers no in-app way to actually resolve a comparison (side-by-side view, decision nudge) — forcing the user to reopen competitor apps or rely on memory.

Result: the comparison resolves silently **off-platform** (a competitor wins — the #1 stated reason for removing an item without buying, 42%), or it **never resolves** (the user forgets — the #1 reason among actual non-converters).

4. Existing User Workarounds

- Keeping multiple shopping apps installed to compare in parallel — 25% check other apps (Ajo, Amazon, Nykaa) before buying a wishlisted item.
- “Keep checking back on it” — manually reopening the wishlist repeatedly, relying on self-directed memory rather than any product-driven prompt.
- Asking friends or family for a second opinion to break a comparison deadlock (11%).
- Passive reliance on notifications respondents describe as easy to miss or ignore.

All four are manual, memory-dependent substitutes for something the product isn't doing: keeping the comparison alive and actionable.

5. Why Solving This Creates Meaningful User Value

Users who let a comparison go cold don't just fail to convert — they lose something they genuinely wanted. They either re-search from scratch later, or the comparison resolves by default (whatever they encounter next) rather than by an actual decision. Helping a user close a comparison they already started is a service to their *original* intent, not an engineered urgency trick — which keeps the solution consistent with the no-monetary-incentive constraint by construction: the fix is decision support and attention, not price.

6. Why Solving This Makes Business Sense

- **opp:comparison_loop** carries the highest purchase-hesitation-link score (0.6338) of all 20 scored opportunities — the AI engine's own formula, independent of raw volume, flags it as most tightly coupled to the actual wishlist-to-buy decision.
- Corroborated by **independent primary research**: dominant in two separate survey questions, and it strengthens when the sample is restricted to true non-converters.
- Avoids over-investing the non-monetary constraint in **opp:returns_exchange** — ranked #1 by raw volume (11.97% of relevant records) but carrying the **lowest** hesitation-link score of the top 10 (0.1074) and **zero** corroboration in the survey — real pain, but post-purchase review-mining bias, not a wishlist-conversion driver.
- Both failure modes (forgetting, losing to an unresolved comparison) sit upstream of checkout — fixing them raises the ceiling on every downstream stage at once.

7. How the Thinking Evolved

Business Metric → **Product Outcomes** → **AI Discovery** → **Primary Research** → **Problem Definition**

→

Stage	What we knew	What it pointed to
Business Metric	% of users who purchase ≥ 1 wishlisted item within 30 days. Monetary incentives excluded.	A single, time-boxed conversion number — undiagnostic on its own.
Product Outcomes	Decomposed into 5 sequential gates: Re-engagement → Uncertainty Resolution → Comparison Resolution → Decision Trigger → Purchase Completion.	A funnel to place evidence against, instead of guessing which barrier “feels” biggest.
AI Discovery	Raw ranking put <code>returns_exchange</code> at #1 by volume. But the engine's own <code>purchase_hesitation_link</code> sub-score ranked <code>comparison_loop</code> highest (0.6338) and <code>returns_exchange</code> lowest (0.1074) of the top 10.	A live contradiction: the “biggest” theme by mentions was not the theme structurally tied to the wishlist decision.
Primary Research	Survey (n=36): comparison was the #1 reason to wishlist (61%) <i>and</i> the #1 reason to abandon without buying (42%). Forgetting was the #1 blocker among non-converters (32%). Returns/exchange: zero mentions.	Confirmed the AI engine's hesitation-link signal and resolved the contradiction.
Problem Definition	Combined all three sources onto one root cause.	The wishlist is a passive bookmark, not a decision workspace — Active Comparers lose the sale by never getting to decide, not by deciding “no.”

Source: `reports/opportunity_register.md` (Phase 5 scoring formula) and the Wishlist Behavior Survey (36 respondents, 22 non-converters).

Supporting Evidence — Volume Rank vs. Wishlist-Relevance Rank

Opportunity	Volume Rank	Hesitation- Link Score	% Relevant (n)	Survey Corroboration
<code>opp:comparison_loop</code>	4	0.6338 (highest)	2.99% (523)	Yes — dominant in 2 questions
<code>opp:intent:uncertain</code>	6	0.5034 (2nd highest)	5.08% (889)	Yes — “forgot about it” is #1 non-converter blocker
<code>opp:returns_exchange</code>	1	0.1074 (lowest)	11.97% (2095)	None — zero mentions

Full ranking: `reports/opportunity_register.md`. Survey tabulation: 36 respondents, 22 non-converters (no purchase from wishlist in 30 days).

Problem Statement

Active Comparers — the largest and most consistently evidenced behavioral segment across both the AI discovery pipeline and the primary-research survey — add items to their Myntra wishlist while genuinely undecided between alternatives, intending to resolve that comparison later. But the wishlist gives them no way to capture what they were comparing, no prompt to return before attention decays, and no way to resolve the comparison inside the app. The comparison is therefore resolved passively: either a competitor wins off-platform (42% of abandoned items), or the user simply forgets the item exists (32% of true non-converters — the single largest blocker). This is not a price problem, a fit problem, or a returns problem — it is a decision-support and re-engagement problem, and it is solvable without any monetary incentive.
